

Lesson problems: Convolution

1 1D discrete convolution

- a) Calculate, step by step by hand, the convolution

$$g(x) = (h * f)(x) = \sum_{\lambda=-\infty}^{\infty} h(x - \lambda)f(\lambda),$$

where $f(x) = (\dots, 0, 0, 1, -1, -2, 0, -1, 1, 2, -1, 0, 0, \dots)$ is the 1D signal and $h(x) = (\dots, 0, 0, 1, 2, -2, 0, 0, \dots)$ is the impulse response, i.e. the 1D convolution kernel. These functions can be represented by the following vectors:

$$f(x) = \begin{bmatrix} 1 & -1 & -2 & \mathbf{0} & -1 & 1 & 2 & -1 \end{bmatrix} \text{ and}$$

$$h(x) = \begin{bmatrix} 1 & \mathbf{2} & -2 \end{bmatrix},$$

where the respective numbers written in bold face are at position $x = 0$. All positions in $f(x)$ and $h(x)$ outside the vectors are equal to zero.

- b) Show how the convolution also can be obtained through a matrix multiplication.

2 2D discrete convolution

Calculate, step by step by hand, the convolution

$$g(x, y) = (h * f)(x, y) = \sum_{\alpha=-\infty}^{\infty} \sum_{\beta=-\infty}^{\infty} h(x - \alpha, y - \beta)f(\alpha, \beta),$$

where

$$f(x, y) = \begin{bmatrix} 1 & \mathbf{2} & 3 \\ 1 & 1 & 1 \end{bmatrix} \text{ is the 2D signal and } h(x, y) = \begin{bmatrix} 1 & \mathbf{3} \\ 2 & 0 \end{bmatrix} \text{ is the}$$

impulse response, i.e. the 2D convolution kernel. In the matrices, the respective numbers written in bold face are at position $(x, y) = (0, 0)$. All positions in $f(x, y)$ and $h(x, y)$ outside the matrices are equal to zero.

3 2D convolution and correlation applied on images

The image $f(x, y)$ on the next page consists of a small 4x4-square of eights "8". Each empty position has value 0. Positions outside the image are omitted,

i.e. when calculating the convolution, those positions can be considered to have value 0. (Here, it is not necessary to define the position $(x, y) = (0, 0)$.)

$gy(x,y)$

- a) In the convolution kernels dx and dy below, the respective bold face center digit "0" is at position $(x, y) = (0, 0)$.

$$dx = \begin{bmatrix} 0.5 & \mathbf{0} & -0.5 \end{bmatrix} = \begin{bmatrix} 1 & \mathbf{0} & -1 \end{bmatrix} / 2, \quad dy = \begin{bmatrix} -0.5 \\ \mathbf{0} \\ 0.5 \end{bmatrix} = \begin{bmatrix} -1 \\ \mathbf{0} \\ 1 \end{bmatrix} / 2$$

Calculate, step by step by hand, the two convolutions

$$gx(x, y) = (dx * f)(x, y) = \sum_{\alpha=-\infty}^{\infty} \sum_{\beta=-\infty}^{\infty} dx(x - \alpha, y - \beta) f(\alpha, \beta),$$

$$gy(x, y) = (dy * f)(x, y) = \sum_{\alpha=-\infty}^{\infty} \sum_{\beta=-\infty}^{\infty} dy(x - \alpha, y - \beta) f(\alpha, \beta).$$

Write the results in the two respective matrices $gx(x, y)$ and $gy(x, y)$ given in the figure above.

- b) Explain from your results how the convolutions with the kernels dx and dy are equivalent to derivation of the image $f(x, y)$ in the x - and y -direction, respectively.
- c) The kernels $vert$ and $horis$ below are equivalent to a 180 degree rotation of the kernels dx and dy , respectively.

$$vert = \begin{bmatrix} -1 & \mathbf{0} & 1 \end{bmatrix} / 2, \quad horis = \begin{bmatrix} 1 \\ \mathbf{0} \\ -1 \end{bmatrix} / 2$$

Calculate, step by step by hand, the two **correlations**

$$g_{vert}(x, y) = (vert \square f)(x, y) = \sum_{\alpha=-\infty}^{\infty} \sum_{\beta=-\infty}^{\infty} vert(\alpha - x, \beta - y) f(\alpha, \beta),$$

$$g_{horis}(x, y) = (horis \square f)(x, y) = \sum_{\alpha=-\infty}^{\infty} \sum_{\beta=-\infty}^{\infty} horis(\alpha - x, \beta - y) f(\alpha, \beta).$$

The symbol \square denotes correlation.

- d) Explain how can you see in your results that the correlations with *vert* and *horis* provide matches for vertical and horizontal edges, respectively, in the image.

4 1D lowpass and bandpass filtering

The pixel values along a horizontal row in an image can be considered as a one dimensional discrete function. Below is one such horizontal row, with pixel values $(\dots, 0, 0, 0, 16, 16, 16, 16, 16, 16, 16, 0, 0, 0, \dots)$, which can be interpreted as a sampled discrete rectangle function, see the top figure below. We assume that all pixel values to the left and to the right of the sequence are zero.

A convolution of this discrete function and the kernel $(1/4, 2/4, 1/4) = (1, 2, 1)/4$ is equal to a low pass filtering of the function, which in turn is equal to blurring along the image row. The bold face "2" is at position 0, as above.

- a) Perform the two-step lowpass filtering (blurring) with the convolution kernel, according to the figure above. Describe in words how the “edges” of the rectangular function are affected by the lowpass filter after each convolution.
- b) The output g_1 of the top subtraction in the figure is equivalent to a highpass filtering of the function f_0 (= the image row) and the output g_2 of the bottom subtraction in the figure is equivalent to a bandpass filtering of the function f_0 .
- Describe in words how smooth surfaces along an image row is affected by a highpass filter and by a bandpass filter.
 - Describe in words how edges along an image row is affected by a highpass filter and by a bandpass filter.

5 The effect of convolution kernels on 2D images

On the next page are the results after the convolutions of the original image above with 6 different convolution kernels A, B, C, D, $E=A*A*A$, and F (an unknown kernel), where

$$A = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} / 4 * \begin{bmatrix} 1 & 2 & 1 \end{bmatrix} / 4 = \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix} / 16, \quad B = \begin{bmatrix} 1 & 0 & -1 \end{bmatrix} / 2,$$

$$C = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix} / 2, \quad D = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix} / 2.$$

Match each resulting image with its corresponding convolution kernel and give a clear motivation for each match.

6 Downsampling

Downsampling by a factor 2 is traditionally carried out by convolving the image with a low pass filtering (blurring) kernel, like for example

$$f = \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix} / 16,$$

followed by a step where every second pixel along both each row and each column are discarded. Finally the image is reshaped to the resulting lower resolution image. (The low pass filtering is needed to avoid so called aliasing.)

- Perform by hand a downsampling by a factor 2 of the image in the figure below. Empty pixels and “pixel positions” outside the image have value 0.
- The stride downsampling method is popular in the field of deep learning. Describe in words how, using this method, you can go directly from the original image to the resulting downsampled image, without performing the intermediate steps.
